Summary

Our group has developed helical foldamers – oligomers that adopt stable helical folded conformations – derived from aromatic amino acids.¹ Some of these folded objects have shown unprecedented conformational stability,² and constitute convenient building blocks to elaborate synthetic, very large (protein-sized) folded architectures (Fig. 1).³ They possess a high propensity to assemble into double, triple and quadruple helices.⁴ Cavities can be designed within such synthetic molecules that enable them to act as artificial receptors⁵ and molecular motors.⁶ Water soluble analogues of these foldamers show promise in nucleic acid recognition.⁷

Figure 1. Crystal structure of a large foldamer comprised of two helices of opposite handedness at a 90° angle. The protein crystal structure on the right is shown as the same scale for size comparison.
